Search Notes

Jim,

Attached is the completed search for the method of injecting bone cement. I did an extensive search on the requested topic in a number of bibliographic and full-text databases as well as on the Internet. I found several items that I think might help you – they are marked with yellow flags. Please be sure to look over all the results as there may be other items of interest. I have attached the search strategies used for the searches performed.

I hope you find this search helpful. If you have a moment, please fill out the attached STIC Feedback Form. And, if there is anything I can do to refine or revise this search, please let me know.

Sincerely,
Ethel Leslie

Voluntary Results Feedback Form

➤ I am an examiner in Workgroup: Example: 3730

➤ Relevant prior art **found**, search results used as follows:

- ☐ 102 rejection
- ☐ 103 rejection
- ☐ Cited as being of interest.
- ☐ Helped examiner better understand the invention.
- ☐ Helped examiner better understand the state of the art in their technology.

Types of relevant prior art found:

- ☐ Foreign Patent(s)
- ☐ Non-Patent Literature
(journal articles, conference proceedings, new product announcements etc.)

➤ Relevant prior art **not found**:

- ☐ Results verified the lack of relevant prior art (helped determine patentability).
- ☐ Results were not useful in determining patentability or understanding the invention.

Mail Box and Bldg/Room Location: _____ Results Format Preferred (circle): PAPER DISK E-MAIL

If more than one search is submitted, please prioritize searches in order of need.

Please provide a detailed statement of the search topic, and describe as specifically as possible the subject matter to be searched. Include the elected species or structures, keywords, synonyms, acronyms, and registry numbers, and combine with the concept or utility of the invention. Define any terms that may have a special meaning. Give examples or relevant citations, authors, etc, if known. Please attach a copy of the cover sheet, pertinent claims, and abstract.

Title of Invention: Method for forming a hardened cement in a lone cavity

Inventors (please provide full names): Jiin-Huey Chern Lin
Chien-Ping Ju

Earliest Priority Filing Date: 3/21/2003

For Sequence Searches Only Please include all pertinent information (parent, child, divisional, or issued patent numbers) along with the appropriate serial number.

Alerting Abstract US A1

NOVELTY - The method involves preparing a cement paste from a powder and a liquid, and **injecting** the **paste** into a pocket (30) on a **bone** cavity. Pressure is applied to the paste before the paste is hardened. A portion of the paste is caused to squeeze out of the pocket, such that the powder/liquid ratio of the paste is increased. The paste in the pocket is allowed to harden and the **pocket** is opened and **separated** from the cement.

USE - Used for forming a hardened cement in a **bone** cavity (claimed).

ADVANTAGE - The method sets the cement paste within the closed pocket without directly contacting body fluid/blood and applies the pressure within the pocket to increase the strength of the cement, thus reducing the risk of cement dispersion/disintegration and avoiding the cement paste leaking. The method easily keeps the powder/liquid ratio of the cement paste accurate by monitoring the pressure build-up within the pocket.

DESCRIPTION OF DRAWINGS - DESCRIPTION OF DRAWING - The drawing shows a cross-sectional view of a device for forming hardened cement in a **bone** cavity.

- 10 Syringe
- 11 Cylindrical tube
- 12 Plug
- 30 Pocket
- 31 Neck

US 20030050702	A1	EN	10	4	

Alerting Abstract US A1

NOVELTY - A grooved director apparatus comprises an elongated rigid tubular stainless steel defining a longitudinal axis with a closed distal tip and an open proximal end portion; an inflatable balloon mounted in the tubular stainless steel; an anchor mounted to the tubular stainless steel; and a pump fluidly connected to the tubular stainless steel to apply selected fluid pressure to the balloon.

DESCRIPTION - A grooved director apparatus to aid in the insertion of a balloon catheter into a vertebra, comprises:

- 1.an elongated rigid tubular stainless steel defining a longitudinal axis with a closed distal tip and an open proximal end portion;
- 2.an inflatable balloon mounted in the tubular stainless steel;
- 3.an anchor mounted to the tubular stainless steel keeping the tubular stainless steel in a fixed position when the balloon is inflated while allowing selective circumferential rotation of the tubular stainless steel when the balloon is deflated; and
- 4.a pump fluidly connected to the tubular stainless steel to apply selected fluid pressure to the balloon.

The tubular stainless steel is cut away from a point along the longitudinal axis to the closed distal tip forming a balloon seat allowing directed expansion of the balloon away from the longitudinal axis toward an area to which compression is to be applied allowing guidance and control of the force of expansion in the vertebra.

An INDEPENDENT CLAIM is also included for a method of expanding a compressed vertebra comprising :

- 1.inserting a grooved director (40) with the built-in balloon into the body of the compressed vertebrae through a trochar insertion sheath;

2. positioning the grooved director with the balloon in a direction under a compressed superior end plate of the vertebral body (20);
3. inflating the balloon (50) so that the force and the direction of the balloon inflation reduces and restores the height of the fractured vertebra;
4. deflating the balloon and rotating the grooved director to a new position within the fractured vertebra and inflating the balloon to create a symmetrical space within the center of the vertebral body;
5. deflating the balloon and removing the grooved director device with the balloon being removed from the trochar insertion sheath;
6. inserting the grooved director without the balloon through the trochar insertion sheath into the space within the center of the vertebral body; and
7. depositing an osteogenic material into the vertebra body.

USE - Used to aid in the insertion of a balloon catheter into a vertebra.

ADVANTAGE - The inventive apparatus is able to guide, concentrate, control and improve the force of balloon compression in a collapsed vertebral body. It can be rotated in the vertebral body to provide selected areas of force against cancerous bone and cortical bone of the vertebral body. It delivers bone graft material or cement into the vertebral body after expansion of same.

DESCRIPTION OF DRAWINGS - The figure is a sectional view of an injection of a grooved director into an interior volume of a vertebra and a balloon expanded against a wall of the damaged vertebra.

20 Vertebral body
40 Grooved director
50 Balloon

Alerting Abstract CA A1

NOVELTY - Visualization of the **injection** of **bone cement** upon **injection** during percutaneous vertebroplasty by fluoroscopic X-ray imaging uses two kits comprising **bone cement**, the second having a greater density enabling it to be viewed distinctly relative to the first.

DESCRIPTION - An apparatus for strengthening and augmenting vertebral bodies by percutaneous vertebroplasty, comprises injection by a minimally invasive percutaneous approach of **bone cement** into the vertebral body, such that structural integrity results. An injection is made by passing a needle down the pedicle until it enters the vertebral body and reaches the junction of the anterior and middle thirds. **Cement** is **injected** under lateral projection fluoroscopy imaging and stopped as it starts to extend into the disc space, the posterior quarter of the vertebral body, or other unwanted location. A second needle is similarly passed down the other pedicle and advanced into the vertebral body to the junction of the anterior and middle third of the vertebral body. **Cement** was mixed with barium and **injected**. Two kits are prepared, such that a first cement batch (kit A) is of a lower yet sufficient density to inject than the second, such that the second batch of cement (kit B) is of greater density making it possible to see it distinct from the first in lateral projection.

USE - The apparatus is useful for strengthening and augmenting vertebral bodies in the treatment of benign osteoporotic fractures, malignant metastatic disease and benign tumors of the **bone** to achieve pain relief

ADVANTAGE - The procedure is minimally invasive, and enable increased structural integrity with decreased micromotion at the fracture site, with a possible destruction of pain fibers due to the heat of the **bone cement** as its polymerizes and sets

Alerting Abstract WO A1

Tool for inserting into **bone** comprising cortical **bone** containing some cancellous **bone** (32), has a guide tube (72), and an expandable body (56) inserted through guide tube in collapsed state. A nozzle is carried by guide tube for insertion into interior volume (30) of the **bone**.

A first lumen (80) is provided to convey medium to expandable body to compact cancellous **bone** and form cavity in interior volume. A second lumen is connected to nozzle to convey material for discharge into cavity. Four systems, six devices and a sterile kit are also independently claimed.

USE - Treating diseased cancellous **bone** by expanding a body within the **bone** to support cortical **bone** and prevent fracture.

ADVANTAGE - The expandable body can be inserted more easily than known methods. It can be used in vertebrae. It can be inserted where access is not along the axis. It can be inserted and deployed in non-symmetrical volumes. A long cavity can be filled. Therapeutic materials can be delivered within the cavity. Material, including **bone** marrow, can be flushed from the cavity.

Alerting Abstract EP A

A plug for restricting flow of cement for fixing an artificial joint prosthesis stem in the canal comprises an expandable elastomer container to fit in the canal with a resealable valve at the end opposite to the inserted into the canal for injection of **inflation** fluid, which is gradually **released** to reduce internal pressure to a min. after a given time.

The container is pref. of silicone elastomer, partic. polydimethylsiloxane, and is inflated with CO2 or He, partic. CO2, which can permeate controllably through the elastomer. The container is pref. generally cylindrical and expands so that its length parallel to the canal axis is at least twice its dia..

USE/ADVANTAGE - E.g. for use with hip joint prosthesis, reduces stressing of canal walls to decrease risk of **bone** resorption and remodelling.

Equivalent Alerting Abstract US A

A **bone** plug for the open-ended intra-medullary canal comprises an elastomeric expandable container, and a valve for injecting bio-compatible fluid under pressure into the container.

The fluid is controllably released into the canal to a min. preselected amount within a predetermined time.

USE - Prevents flow of **bone** cement into the canal during artificial joint insertion. (11pp)

Alerting Abstract US A1

NOVELTY - Bone treatment involves inserting a device into the interior area of bone tissue to be treated, and internally supporting the bone tissue using the device during treatment.

DESCRIPTION - An INDEPENDENT CLAIM is also included for treating device, comprising a catheter, and expandable semi-compliant structure, and a removable fastener, which connects the catheter to the semi-compliant structure.

USE - For use during treatment of osteoporosis, osteoporotic fractured metaphyseal and epiphyseal bones, osteoporotic vertebrae, fractures of vertebrae due to tumors, round cell tumors, avascular necrosis of epiphyses of long bones, avascular necrosis of proximal femur, distal femur and proximal humerus, defects resulting from endocrine conditions, metastatic tumors, and fracture of cervical, thoracic, lumbar and sacral fractures (claimed).

ADVANTAGE - The exfiltration of the bone support material from the fracture site is prevented by the sealable port. The infiltration of the biological fluid into the semi-compliant structure is prevented so as to improve durability of the semi-compliant structure by preventing corrosion and degradation of its walls. The semi-compliant structure is removed from the fracture site easily, without damaging the bone tissue.

DESCRIPTION OF DRAWINGS - The figure shows a side view of the semi-compliant structure and catheter in cancellous bone of vertebrae.

17 Cancellous bone tissue
49 Semi-compliant structure
67 Catheter
74 Cavity

Alerting Abstract US A1

NOVELTY - A cavity creation device comprises a holding sleeve to contain an elastomeric material, in co-axial communication with a bumper; and a plunger for insertion in the holding sleeve. When the sleeve contains an elastomeric material and the plunger is inserted into the sleeve, operation of the plunger forces the elastomeric material against the bumper. The bumper causes the elastomeric material forced against it to expand and create a cavity.

DESCRIPTION - INDEPENDENT CLAIMS are also included for:

- 1.a kit for assembly into a device for creating a cavity in mammalian tissue comprising a bumper, a holding sleeve for operative communication with the bumper, an elastomeric material for insertion into the holding sleeve, and a plunger for insertion into the holding sleeve;
- 2.a device for creating and filling a cavity in a mammalian body comprising an apparatus for dispensing a biocompatible filler, and an elastomeric casing attached to the apparatus; and
- 3.a method for creating and filling a cavity in a mammalian tissue comprising inserting an elastomeric casing in the tissue, and filling the casing with a biocompatible filler to expand the casing.

USE - For cavity creation in a mammalian **bone** tissue, e.g. cancellous **bone** tissue of mammalian vertebrae, by inserting the elastomeric material into the tissue, **expanding** and contracting the material, and **removing** the material from the tissue (claimed).

ADVANTAGE - The invention allows the elastomeric material to resume its original shape

DESCRIPTION OF DRAWINGS - The figure shows a perspective view of a cavity creation assembly.

1050 Delivery tube device
1060 Delivery tube device handle
1070 Elastomer
1090 Guide rod
1100 Bumper

Alerting Abstract WO A2

NOVELTY - A **bone** fixture apparatus comprises a pliable insert (72) for engaging a fixing device and at least one tapered hole to receive the respective fixing device. The pliable material is settable, self-expanding and biodegradable or bioabsorbable.

DESCRIPTION - INDEPENDENT CLAIMS are included for the following:

- 1.a method of supporting a fractured bone ; and
- 2.the pliable insert for engaging a bone fixture apparatus.

USE - As a **bone** plate or intra-medullary nail (claimed) for supporting a fractured **bone** .

ADVANTAGE - The pliable insert allows the screw to be driven through the plate etc. a number of times of different angles. The biodegradable material is firmly attached to the **bone** without allowing any movement only in the initial phase of the fracture, so that it can take the loading normally applied to the fractured area of **bone** arising from everyday use. The biodegradable insert can assist in removal of implant, as by time the **bone** has healed, the pliable material would have been eroded, and the fixing can be more easily **removed** . The settable and self- **expanding** pliable material can change phase (e.g. from **paste** , gel or liquid to a solid) on application of pressure or heat, when exposed to a chemical catalyst, or after an interval of time. Increased grip between screw and cylinder, and between the cylinder and nail helps to keep the screw stationary with respect to the nail, thus preventing or restraining movement of the nail in the **bone** which can disrupt the healing process. The insert can be inserted into the hole without any external heating or special application of extra force, so the insert can easily be inserted into any suitable hole at any time before or during the operation with an easy press-fit. The axis of the screw is not co-axial with axis of the hole to allow the selection of the angle of insertion of the screw, without surgeon being forced to change the orientation of the hole or the **bone** plate.

DESCRIPTION OF DRAWINGS - The figure shows a cross-sectional view of the **bone** plate and pliable insert, having a screw driven through the insert.

- 64' Hole
- 66 Upper surface of plate
- 68 Lower surface of plate
- 72 Insert
- 82 Screw
- 84 Screw head
- 86 Shaft of screw

Alerting Abstract US A1

NOVELTY - Tissue anchoring device (10) comprises implant (11) made of flexible wall, sutures fastened with the implant, and pasty medicine. The implant is provided with holding portion and injection port. The injection port is in communication with holding portion. The holding portion is enclosed by flexible wall provided with pores. Each pore has diameter smaller than 0.1 mm. The implant is contractible and is contracted prior to being inserted into bone .

DESCRIPTION - Tissue anchoring device comprises an implant made of flexible wall (111, 112), sutures fastened with the implant, and pasty medicine. The implant is provided with a holding portion (114) and an injection port (115). The injection port is in communication with the holding portion. The holding portion is enclosed by the flexible wall provided with pores (113). Each pore has a diameter smaller than 0.1 mm. The implant is contractible and is contracted prior to being inserted into the bone . The pasty medicine is capable of solidification injected into

the holding portion via the injection port of the implant in the wake of insertion of the implant into the **bone** , thus resulting in expansion of the implant to enable the implant to be securely lodged in the **bone** upon completion of the solidification of the pasty medicine.

USE - For use in anchoring tissue to **bone** in surgical operation.

ADVANTAGE - The invention provides good anchoring effect. It allows sutures to be integrally knitted to the flexible wall of implant without forming the thread hole.

DESCRIPTION OF DRAWINGS - The figure shows perspective view of the implants and surgical sutures of the invention.

NOVELTY - A shield (30) has coaxial shield structures with distal end (32), proximal end and flexible beam portions extending along an inflatable elastomeric sleeve (23). The beam portions curve outwards with inflation of the sleeve, and the central portions of the beam, are separated from each other. An elongated insertion tool (16) connected to the sleeve, has a passage for the fluid injected into the passage of core (12).

USE - For plugging open end of intramedullary **bone** canal to restrict flow of **bone** select during fixation of stem of artificial joint prosthesis to end of **bone**, and also during fixation of hip joint prosthesis to proximal femur.

ADVANTAGE - Shield is more resistant to damage from sharp objects and the **bone** plug having elastomeric sleeve is protected from puncture by **bone** splinters and sharp **bone** edges.

DESCRIPTION OF DRAWINGS - The figure shows the longitudinal cross-sectional view of **bone** plug.

- 12 core
- 16 insertion tool
- 23 elastomeric sleeve
- 30 shield
- 32 distal end

Alerting Abstract WO A2

NOVELTY - An in situ formable orthopedic fixation rod, comprises an elongated tubular balloon (114) having an interior chamber and inflatable from a first insertion profile to second, enlarged profile and an accelerator for accelerating the curing of a curable media into the chamber.

DESCRIPTION - INDEPENDENT CLAIMS are also included for the following:

1. an orthopedic fixation device (102) which comprises an elongated flexible tubular body (TB) (104) having a distal end (108) and proximal end (106) body forming a central lumen, manifold (124) at the proximal end with an inflatable member (IM) having proximal and distal ends and an interior removably attached to distal end, heat source in thermal communication with interior of IM and valve provided at proximal end;

- 2.a method for stabilizing an orthopedic fracture which involves inserting two anchors with portals into a bone , delivering an orthopedic device with balloon to the bone , inflating balloon with stiffening material and heating the media above body temperature to accelerate stiffening of the stiffening material. The orthopedic device extends through portals, such that inflating fixes and anchors in relation to one another;
- 3.a method for forming an orthopedic device at a treatment site within the body of a patient which involves positioning an outer wall at the treatment site in which the outer wall forming a chamber, introducing a hardenable media into the chamber and heating the media to accelerate hardening to form orthopedic device;
- 4.a method for treating a patient which involves securing a first rod at first site in patient, securing a second rod at second site, introducing a curable media between first and second rods to form a cross link and heating the media at 50(deg)C to accelerate curing of the media thereby linking the first rod to the second rod; and
- 5.a deployment catheter for deploying an implantable inflatable orthopedic device which comprises an elongated flexible TB, inflatable device removably carried by distal end, energy source connected to proximal end and heating element in thermal communication with the inflatable device.

USE - For forming implantable and inflatable orthopedic fixation and for stabilizing implants within the body.

ADVANTAGE - The device enables the access treatment site within the body by using minimally invasive procedures.

DESCRIPTION OF DRAWINGS - The figure shows a side elevational view of delivery catheter with inflatable fixation device.

- 100 Delivery catheter
- 102 Orthopedic fixation device
- 104 Tubular body
- 106 Proximal end of tubular body
- 108 Distal end of tubular body
- 110 Inner sleeve
- 112 Outer sleeve
- 114 Balloon
- 120 Reinforcement element
- 122 Stiffening wire
- 124 Manifold

Alerting Abstract US B1

NOVELTY - An apparatus for stopping flow of **bone cement** through a channel comprises a **bone** plug and an elongated insertion tool (EIT). The **bone** plug includes an inflatable structure (IS), a core and a shield which is more resistance to damage from sharp objects than IS. The EIT is removably connected to the core and includes a tool passageway for fluid injected into the core passageway.

DESCRIPTION - An apparatus for plugging a channel within a **bone** to stop the flow of **bone cement** through the channel comprises a **bone** plug (10) and an elongated insertion tool (EIT). The **bone** plug which is insertable within the channel includes an inflatable structure (IS), a core (12) with a distal portion extending beyond a distal portion of IS and attached to IS, a shield (30) extending from the distal portion of the core outwardly around and along IS and a valve admitting a fluid (38) into IS and preventing a flow of fluid from IS. The core includes a core passageway for the fluid injected into the inflatable structure. The shield which expands with inflation of IS is substantially more resistance to damage from sharp objects than IS. The EIT is removably connected to the core and includes a tool passageway for the fluid injected into the core passageway.

USE - The invention is a medical device for use in the implantation of joint prosthesis at the end of a **bone** and is also used as a plug for stopping the flow of **bone cement** (claimed).

ADVANTAGE - Since the **bone** plug has an elastomeric inflatable structure, the **bone** plug is protected from puncture by **bone** splinters and sharp **bone** edges. The shield structure expands greatly without stretching the material. The invention is easily manufactured and the plug and insertion tool are easily disconnected once proper insertion has been undertaken.

DESCRIPTION OF DRAWINGS - The figure shows the longitudinal cross-sectional view of the **bone** plug with the inflatable sleeve in a fully inflated condition.

10bone plug

Alerting Abstract WO A2

NOVELTY - A vertebral compression fracture is treated or prevented by inserting an insertion device into a vertebral body; inserting a cavity-forming device through the insertion device into a cancellous **bone** (115) in the vertebral body (105); displacing cancellous **bone** to create a cavity (170) and a barrier region of compressed cancellous **bone** ; and filling the cavity with a filler (180).

DESCRIPTION - An INDEPENDENT CLAIM is also included for a balloon catheter comprising a lumen within the tube, an expandable material, and an opening communicating with the lumen.

USE - For treating, i.e. repairing, reinforcing, and/or treating fractured and/or diseased **bone** .

ADVANTAGE - The method obviates the need for high pressure injection of **bone** filler, thus reducing the possibilities of **cement** leakage and/or extravazation outside of the **bone** . The creation of flow paths permits greater control in the placement of the **bone** filler material within the

vertebral body.

DESCRIPTION OF DRAWINGS - The figure is a lateral view of a lumbar vertebra.

105 Vertebral body
115 Cancellous bone
170 Cavity
180 Filler

Alerting Abstract GB A

The system has a conduit (18), which includes a flexible, single or multiple lumen catheter that is enveloped near a distal end by an inflatable body (16). One or more openings (24) in the catheter (18) near the distal end permit fluid to be introduced and evacuated from the inflatable body.

An intermediate portion of the catheter with the integral inflatable body is within an internal passage of a (semi) rigid tubular guide (26), while an apertured shield (20) abuts a distal end of the tubular, and a portion of the catheter extends through the aperture and beyond the shield. The shield is releasably engageable with the tubular guide so that the tubular guide can be used to position the shield within the medullar canal and then be separated from the shield.

USE - For arthroplasty procedures such as total hip replacement

ADVANTAGE - Well suited to revision arthroplasty. Allows creation of the cement plug at any selected point within the long bone, including points beyond the isthmus.

Alerting Abstract US A

The balloon catheter, for an internal fixation of fractures of tubular bones , has a number of guide wires for its passage through the medullary canal and fracture site of the bone . A bone cement is applied to the fracture site, and the balloon is expanded while pressure is applied to the catheter outside the bone to apply a compression force across the fracture site for increased stability and promoting bone healing.

ADVANTAGE - The appts. minimises damage to the interior blood vessels and periosteum of the bone , and allows the guide wires to be removed. It also allows the use of a biodegradable bone cement .

Alerting Abstract EP A

The shape of the root of a prosthesis for anchorage in the core of part of a human or animal **skeleton** is determined by making a cast (7) of a cavity prepared in the **bone** and using the resulting casting as a guide for machining the body of the root of the prosthesis from a material suitable for long term use. The casting is made from a cold setting material (I) sufficiently elastic to be withdrawn from minor undercut profiles within a medullar cavity without permanent deformation. The withdrawn casting is scanned to detect any high points and the (numerically controlled) cutting machine instructions for making the permanent root are modified to eliminate such high points so that a rigid root can be accepted to a close fit by the cavity, with a thin but sufficient interface of cement to cover the surface and pack the undercut zones to provide a good key.

Pref. (I) if a polysiloxane based rubber. Opt. the cavity is first lined with a loose sheath of elastic flexible material which is not adherent to either the **bone** or the rubber, pref. polyethylene film (4), which can be withdrawn together with and then sepd. from the cast model for the root. A reinforcing rod (9) may be set into the casting before it cures, to support the base for a model of the external part (11) of the prostheses and for remote support of the root during dimensional scanning.

USE - Esp. suitable for anchoring artificial joints, e.g. for hips, knees, elbows, to avoid the use of screwed anchorates which are liable to work loose.

Title Terms/Index Terms/Additional Words: CAST; MODEL; SHAPE; ROOT; **SKELETON** ; PROSTHESIS; PREFER; SILICONE; RUBBER; POLYETHYLENE; FILM; SHEATH; PERMIT; WITHDRAW; ROUGH; CAVITY

Alerting Abstract EP A

A joint prosthesis comprises an adaptor component, and a prepreg component connected to it; the prepreg component is inserted into the **bone** cavity before it is hardened, and an internal, inflatable bag is pressurised to cause the prepreg component to bear firmly against the inner face of the **bone** before it hardens. The inflating fluid is pref. introduced through a perforated pipe.

The device easily adapts to the individual form of the **bone** of the patient. An ultraviolet light or ultrasonic emitter is pref. introduced through the tube to harden the prepreg component.

Equivalent Alerting Abstract US A

A joint prosthesis for insertion in an intramedullary cavity comprises an adapter having an entry nipple, a hollow flexible prepreg member of **hardenable material** attached to the adapter, and a hollow, **inflatable** fluid-impervious pressing **bag removable** receivable in the prepreg member. The prepreg member after introduction into the intramedullary cavity is inflated by fluid entering the pressing bag from the adapter nipple which causes the bag to expand. The prepreg member is eventually forced by the bag to conform to the surface of the intramedullary cavity where, upon hardening, the prepreg member forms a hard shell constituting the sole anchoring member of the prosthesis. The prepreg may be a fibre structure wetted, but not yet hardened, with a plastic.

ADVANTAGE - The joint is strong and there is less chance of loosening. (8pp)

Alerting Abstract DE A

The instrument removes a **bone cement** tube from a cavity in a thigh-**bone** on reimplantation of an artificial thigh-**bone** neck head, having an extractor for securing to the tube.

The extractor (2) is a hollow tube, inside which an actuating bar (11) for an expander (17) is guided, the expander being below and concentric to the tube. One end (4) of the latter can have an external thread, screwing into a thread tapped in the **cement** tube, and control surfaces can also be provided at this end for the expander.

Equivalent Alerting Abstract US A

The instrument for removal of a hollow **bone cement** tube from a femur reimplantation has an elongate hollow tube inserted into the **bone cement** tube. This is then removed with a collet at the insertion end of the hollow tube which is radially expanded to engage the **bone cement** tube on the interior by rotation of a mandrel having the collet threadedly engaged on the insertion end.

The hollow tube engages the collet to prevent relative rotation with it and to allow the mandrel by threaded engagement with the collect to effect the radial expansion.

ADVANTAGE - The radial forces on the **bone** may be completely eliminated, particularly when the **bone** tube is ejected, while at the same time enabling complete removal of the **bone cement** from the femur. (5pp)

Alerting Abstract EP A2

NOVELTY - The system includes a sleeve (12), designed to be secured by **bone cement** within a cavity (54) prepared in the end of a **bone**. Its bore is tapered to match the stem of the joint prosthesis to be fitted. A plug (10), tapered to fit the sleeve's bore, slides with it on a guide rod (14) during installation. The rod, plug and pilot shaft (18) are part of a modular alignment system which is **removed** when the **sleeve** is in place.

DESCRIPTION - A pilot shaft of appropriate length is selected and positioned, with the guide rod attached, in the prepared **bone** canal (52) at the required alignment. The seal is positioned to define the base of a cavity which is then filled with **bone cement**. The plug/sleeve assembly is then slid down the guide rod until the sleeve is at the required position in the cavity, the plug preventing **cement** ingress into the sleeve's bore. The rod, plug and shaft are removed when the **cement** is sufficiently hard. Finally, a joint prosthesis is fitted into the tapered bore of the sleeve.

USE - As a system for placing a **cementless** joint prosthesis in a controlled alignment into a sleeve **cemented** into a **bone** cavity.

ADVANTAGE - The system allows the sleeve to be firmly **cemented** within a **bone** cavity without the risk of **cement** fouling its tapered bore. The sleeve's alignment can be accurately established during installation, and its tapered bore provides a **cementless** connection to a matching joint prosthesis which can, if required, subsequently be removed without damaging the **bone**.

DESCRIPTION OF DRAWINGS - The drawing shows a longitudinal section through a femur into which the plug and sleeve have been fitted.

- 10 Plug
- 12 Sleeve
- 16 Seal
- 14 Guide rod
- 18 Pilot shaft
- 52 **Bone** canal
- 54 **Bone** cavity

Alerting Abstract WO A1

Bioactive glass or ceramic material (A), which has been treated prior to contact with anchorage-dependent cells to achieve greater cellular attachment strength, is new.

Also claimed are:

- (1) an implant (B) comprising a substrate of bioactive glass or ceramic treated to achieve greater anchorage-dependent cell attachment;
- (2) a method for forming tissue made by anchorage-dependent cells in vitro, comprising:
 - (a) providing a substrate formed of a bioactive material;
 - (b) immersing the substrate in a first aqueous solution containing ions in a concentration typical for interstitial fluid;
 - (c) immersing the substrate in a second aqueous solution containing ≥ 1 cell adhesion molecule (CAM), and
 - (d) inoculating the substrate with cells in tissue culture medium;
- (3) a method for forming tissue made by anchorage-dependent cells in vitro, comprising:
 - (a) providing a substrate formed of a bioactive material;
 - (b) immersing the substrate in a first aqueous solution containing ions in a concentration typical for interstitial fluid;
 - (c) immersing the substrate in a second aqueous solution containing a first CAM at a non-saturating concentration;
 - (d) immersing the substrate in a third aqueous solution containing a second CAM, and
 - (e) inoculating the substrate with cells in tissue culture medium;
- (4) preparing a substrate for attachment of anchorage-dependent cells, comprising steps (a), (b) and (c) of process (2) above, and
- (5) preparing a substrate for attachment of anchorage-dependent cells, comprising steps (a), (b), (c) and (d) as described in (3) above.

USE - The processes are used for synthesis of bioactive ceramic and glass templates for optimum in vitro formation of **bone** and **bone**-like tissue. The products may be used in, e.g. primary joint replacement. Typically, a porous coated prosthesis is surrounded by a **sleeve** of the **porous** template material prepared as outlined above, and seeded with cells.

USE - After one to two weeks, the product is implanted into the patient.

ADVANTAGE - The bioactive glass/ceramic materials permit in vitro formation of **bone** tissue when exposed to a tissue culture medium and inoculated with cells.

Alerting Abstract EP A1

The femur prosthesis comprises a shaft (2) which is enclosed by an extensible sheath (4) of biocompatible polymeric material. When **cement** is applied, the sheath is continuously filled from the distal to the proximal side. When the space (5) between the shaft (2) and **bone** support (6) is completely filled, the sheath is pressed against the **bone** support.

The proximal part of the sheath is fixed to spacer pieces (7) serving to centre and align the prosthesis. The **sheath** has **pores** which widen when the **sheath** is filled with **cement** at the back.

ADVANTAGE - Avoids contamination of the prosthesis surface and the applied **cement** from blood, secretion and fluid.

Alerting Abstract EP A1

Prosthesis has part (4) insertible into or attachable to **bone** without **bone cement** and which is covered by synthetic resin mantle (7) having roughened outer surface (10) and which is preformed as separate component before fitting to the prosthesis. The mantle is pref. of acrylic **bone cement** and the depth of the roughened surface is 0.5-5 mm.

The mantle outer surface may incorporate natural or synthetic **bone** chippings (13), or may have coating (11) of bioactive hydroxyapatite or

bioglass and have coating of particles of Ca phosphate, partic.
hydroxyapatite or tricalcium phosphate, embedded in the surface.
Alternatively, the roughened surface may be formed by embedded fragments
(24) of Ca sulphate, hydroxyapatite or **bone** .

USE/ADVANTAGE - Used e.g. for hip or knee prostheses, eliminates the
time-consuming procedure of using fresh **bone cement** with its associated
danger of toxicity.

Alerting Abstract EP A

A perforated sheath of acrylics is designed to cover a stem of an intramedullary prosthesis from its distal end to adjacent the proximal cut end of the femur. Pref. the stem is constructed to allow the prosthesis to move into it under load. Pref. centralisers (14) are provided. Pref. the sheath is made of material similar to **bone cement** e.g. polymethylmethacrylate.

ADVANTAGE - Reduces the chance of cracks or gaps forming between the prosthesis, **bone** and **cement** . @(6pp Dwg.No.1/2)@

Equivalent Alerting Abstract US A

Prosthetic intramedullary femoral prosthesis comprises a stem and a **separate** preformed **sheath** made from an acrylic material dimensioned to enclose the stem from its distal tip to an adjacent location on the stem to the proximal cut end of the femur being used.

Sheath has same shape as the stem, but extends further in the distal direction to form a void between the distal tip and that of the stem. Sheath slidably receives the stem to allow axial movement between them over the length of the stem after implantation. Sheath has thickness of 0.5-2mm.

ADVANTAGE - Interface conditions between the **cement** in an intramedullary canal and the surface of the stem are optimised.

Alerting Abstract US A

The flexible therapeutic anatomical support is of form-fitting, compressive, heat-retaining elastic foam material the supportive, compressive and movement resisting forces of which are selectively reinforced and relieved, for supporting, protecting and resisting the movement of the muscles and **skeletal** structure at joints and other limb area during presurgery conditioning post-trauma, and post-surgery convalescence. A limb-ensheating sleeve of sufficient length to cover the affected portion of the limb is fabricated from a sheet of foam neoprene material bent around to form a tube and adhesively secured at its seam edges with contact element.

Temporosphenoidal encephaloceles are rare entities that occur when the temporal lobe herniates into the sphenoid sinus through a skull base defect of the temporal **bone** . Both an iatrogenic and a traumatic pathogenesis have been proposed. The authors describe a spontaneously occurring temporosphenoidal encephalocele in a 63-year-old woman who had a 4-year history of rhinorrhea. Spiral computerized tomography (CT) scanning revealed a **bone** defect located inside the ophthalmomaxillary triangle. The intrasphenoidal encephalocele had a heterogeneously hypointense signal compared with cerebrospinal fluid (CSF) on T1-weighted magnetic resonance (MR) images and a hyperintense signal compared with CSF on T2-weighted MR images. Two previous endonasal endoscopic procedures, performed by ear, nose, and throat surgeons, had been unsuccessful. The authors performed an endoscopic endonasal right nostril procedure by using 0 degrees and 45 degrees rigid-lens endoscopes that were 4 mm in diameter and 18 cm long. The encephalocele in the sphenoid sinus was partially removed. DuraGen and fat graft were positioned in the **bone** defect. Two No. 2 French **detachable silicone balloons** (1.5 cm3 volume) inflated with surgical glue were introduced into the skull defect and into the sphenoid sinus, respectively. The CSF leakage stopped immediately. No nasal packing or postoperative CSF lumbar drainage was necessary. The patient did well. Postoperative CT and MR imaging, obtained at 24 hours and at 3 months, demonstrated that the balloon and the fat graft filled the **bone** defect and the sphenoid sinus. Eight months postprocedure no CSF leakage was observed. This appears to be the first case reported in the literature of a temporosphenoidal encephalocele successfully treated by an endoscopic endonasal technique involving packing of the defect with **inflated detachable balloons** .

Objective: Restoration of height of a fractured vertebral body with an inflatable balloon system introduced transpedicularly into the vertebral body. The system creates a cavity that is filled with **bone cement**. This minimally invasive procedure creates an internal stabilization.

Indications: Osteoporotic vertebral compression fractures with an intact posterior wall. Osteolytic metastases. Primary benign vertebral tumors such as hemangiomas. Traumatic compression fractures with an intact posterior wall. Contraindications: Unstable burst fractures involving the posterior wall. Coagulopathies. Disk herniation accompanied by radiculopathy.

Compression of entire vertebral body (vertebra plana). Surgical Technique: In prone position and under fluoroscopic control transpedicular placement of Jamshidi needles into the posterior third of the vertebral body through stab incisions. Insertion of guide wires through these needles for proper placement of working cannulae. Drilling of a channel for insertion of the balloon system. Under fluoroscopy in two planes, pressure-controlled filling of the balloon with a contrast medium. Once the proper vertebral height has been obtained, **removal** of contrast medium and **balloon** and filling of the cavity with **cement** avoiding any leakage into the spinal canal. Once the **cement** has hardened, removal of working cannulae, skin closure. Results: In a prospective study of 95 patients (165 vertebral bodies) with osteoporotic fractures treated with PMMA **cement** or calcium phosphate filling, we observed a marked symptom reduction in 89%. The average restoration of height amounted to 16%. **Cement** leakage not leading to any complications occurred in 14 vertebral bodies (8%), a percentage far below published values of 20-70%. LANGUAGE: FRENCH SUMMARY LANGUAGE: ENGLISH; FRENCH

Purpose of the study: We report our first eleven uses of a new **cement** mantle extraction system. The basis of this technique relies on a **cement bone** interface with a lower strength compared to the old **cement - new cement** interface. Material and methods: The first stage of the procedure consists in a specific preparation of the inner surface of the old **cement** mantle. It should be clean and dry after being abraded with a stainless steel wire brush. Then a thin **cement** syringe filled with low Viscosity PMMA **cement**, is injected in the old mantle in a retrograde fashion. A threaded rod with nuts is centered within the **cement** sheath to the bottom and held until the injected **cement** has fully polymerised. Then the threaded rod is unscrewed from the femur; nuts are established along the entire length of the **cement** column. To prevent trochanteric fracture occurring upon **cement** extraction, it is important to clear away sufficient **bone** from the lateral aspect of the canal. A series of extraction rods are then used to sequentially remove the **cement** mantle. The removal rod is screwed back into the threaded channel at a distance of every one to three nuts, and then attached to the slap hammer via a quick release connection. **Cement** extraction is performed using deliberate slaps of the slap hammer. The last segment is drilled with the use of a distal plug drill centering **sleeve**. After having inserted the plug **removal** rod, the last segment is extracted. We used this technique eleven times in 8 hips for 5 loosening of femoral component and 3 revisions hip arthroplasties without loosening and 2 revisions knee arthroplasties without loosening (an extraction system for the femur and the tibia). Results: For the 5 loosening cases extraction was easy. In 2 cases, **cement** mantle was removed as a single 'en bloc' piece. In the 3 other cases, the extraction was segmental only in the distal third of the **cement** mantle. Without loosening, the extraction was completely segmental. In all cases, **cement** mantles were successfully removed. There was no fracture and no loss of **bone** stock. There was only one 'fissuration' of the great trochanter and we only made one distal window. All hip arthroplasties were replaced and arthrodesis were performed after removal of the knee arthroplasties. Discussion: The **cement** -assisted mantle removal technique appears to be a simple, quick and effective methods for **cement** mantle removal. Perforation and diaphyseal window can be avoided by the technique even when loosening does not exist. However, it is necessary to establish a thorough preoperating plan in order to eliminate contraindications such as too narrow or too curved sheath. Conclusion: It appears that this new procedure will facilitate future reoperations which are reputed to be

difficult and dangerous.
